Overview

- Binary classification: notations
- Combining classifiers
- Heuristics of boosting algorithms
- Main result on consistency
- Extensions of the main result
- Simulations results

Binary classification

Observation: $X \in \mathbb{R}^d$, distribution μ

Label/Class: $Y \in \{-1, +1\}$

Regression function:

$$\eta(x) = \mathbb{P}\left\{Y = 1 | X = x\right\}$$

Data sample:

$$D_n = \{(X_1, Y_1), ..., (X_n, Y_n)\}$$
 i.i.d.

Classifier:

makes a prediction $g_n(X) \in \{-1, +1\}$

A performance/error measure:

$$L(g_n) = \mathbb{P}\left\{g_n(X) \neq Y \mid D_n\right\} = \mathbb{E}\mathbb{I}_{\left\{Y \cdot g_n(X) < 0\right\}}$$

Bayes classifier and error:

$$g^* = \underset{\text{all } g}{\operatorname{arg \, min}} L(g)$$

 $L^* = L(g^*) = \mathbb{E}\{\underset{\text{min}}{\operatorname{min}}(\eta(X), 1 - \eta(X))\}$

Learning

Inputs:

- ullet a model class ${\mathcal C}$ of indicator functions
- a sample-based criterion:

$$\min_{g \in \mathcal{C}} K(g, D_n)$$

Output: a classifier g_n

Goal of learning:

minimize generalization error $L(g_n) \ge L^*$

Examples of learning algorithms:

perceptron, neural networks, decision trees

Learning (2)

Complexity trade-off: estimation vs. approximation

$$L(g_n) - L^* = (L(g_n) - \inf_{g \in \mathcal{C}} L(g)) + (\inf_{g \in \mathcal{C}} L(g) - L^*)$$

Empirical risk minimization:

$$g_n = \operatorname*{arg\,min}_{g \in \mathcal{C}} \left(\widehat{L}_n(g) := \frac{1}{n} \sum_{i=1}^n \mathbb{I}_{\{Y_i g(X_i) < 0\}} \right)$$

From Vapnik-Chervonenkis (VC) theory:

If the class C is not "too large" (finite VC dimension):

$$L(g_n) - \inf_{g \in \mathcal{C}} L(g) \to 0$$
 a.s.

However: a poor class often leads to poor performance...

Solutions: increase class complexity or combine!

Combination methods

 Π_1 distribution over $D_n \to \text{select } h_1 \in \mathcal{C}$

. . .

 Π_t distribution over $D_n \to \text{select } h_t \in \mathcal{C}$

. . .

Final prediction:

$$g_n(X) = \operatorname{sign}\left(\sum_t w_t h_t(X)\right)$$

where

- uniform weights \rightarrow Bagging Π_t distribution of a bootstrap subsample
- adaptive weights \to Boosting $w_t = \frac{1}{2} \log \left(\frac{1 \epsilon_t}{\epsilon_t} \right)$

 Π_t updated iteratively from Π_{t-1}

Combination methods

Estimator: $f = \sum_{i} w_i h_i \in \mathcal{F}$,

where $h_i \in \mathcal{C}$, w_i are (convex) weights.

Model class: $\mathcal{F} = \mathcal{L}(\mathcal{C})$ or $conv(\mathcal{C})$

Classifier: g(X) = sign f(X)

Remarks:

- convex hulls of simple classes have infinite complexity
- derived algorithms are amazingly efficient

Open question:

Do boosting algorithms overfit?

Formally: Statistical consistency? Practical efficiency?

Leo Breiman: "understanding why boosting works is the main open problem in Machine Learning".

Previous work

Origins: Schapire (1990), Freund and Schapire (1995, 1996) for boosting, Breiman (1996) for bagging

Empirical studies: too many!!!

 \rightarrow visit www.boosting.org

Boosting as gradient descent: Breiman (1997) Friedman-Hastie-Tibshirani (1998), Collins-Schapire-Singer (2000), Mason-Bartlett-Baxter-Frean (1999).

Margin analysis:

Schapire-Freund-Bartlett-Lee (1998), Koltchinskii-Panchenko (2000), Blanchard (2001)

About consistency: only very recent work from Breiman (2000), Jiang (2000, 2001), Mannor-Meir-Mendelson (2001), Bühlmann-Yu (2001), Zhang (2001), Mannor-Meir-Zhang (2002).

Common belief

Observation:

$$L(g) = L(f) \le A(f) = \mathbb{E} \exp(-Y \cdot f(X))$$

Empirical criterion:

$$A_n(f) = \frac{1}{n} \sum_{i=1}^n \exp(-Y_i f(X_i))$$

Minimizers:

$$\widehat{f}_n = \operatorname*{arg\,min}_{\mathcal{F}} A_n(f)$$

$$f^* = \underset{\text{all } f}{\operatorname{arg \, min}} A(f) = \frac{1}{2} \log \left(\frac{\eta}{1 - \eta} \right)$$

Hopefully:

$$L(\widehat{f_n}) \to L(f^*) = L^*$$
, almost surely

Our challenge: prove it!!!

More notations

Let $\phi: \mathbb{R} \to \mathbb{R}_+$

- strictly increasing,
- strictly convex,
- $\phi(x) \ge \mathbb{I}_{[x \ge 0]}$ for all $x \in \mathbb{R}$,
- $\lim_{x \to -\infty} \phi(x) = 0$

Cost functional:

$$A^{\lambda}(f) = A(\lambda f) = \mathbb{E}\phi(-\lambda Y \cdot f(X))$$
.

where λ is a smoothing parameter.

Empirical cost functional:

$$A_n^{\lambda}(f) = \frac{1}{n} \sum_{i=1}^n \phi(-\lambda Y_i \cdot f(X_i)) .$$

Typical example: $\phi = \exp$

 \rightarrow other choices? ...

Main result

Assume

- $\mathcal{F} = \text{conv}(\mathcal{C})$ contains the indicators of all subrectangles of \mathbb{R}^d
- Let λ_n such that $\lambda_n \to \infty$ and

$$\lambda_n \phi'(\lambda_n) \sqrt{\frac{\ln n}{n}} \to 0 \quad \text{as } n \to \infty$$

•
$$f_n = \widehat{f}_n^{\lambda_n} = \operatorname{arg\,min}_{f \in \mathcal{F}} A_n^{\lambda_n}(f) \in \mathcal{F}$$

Then, we have

$$\lim_{n \to \infty} L(f_n) = L^* \quad \text{almost surely.}$$

Comments

Universal result: noise-resistant strategy

Denseness assumption: fulfilled by decision trees with T > d terminal nodes

Key of the result: the smoothing parameter λ governs complexity trade-off

- accurate estimation $\rightarrow \lambda$ small
- ullet reduce approximation error $o \lambda$ large

First simple lemma

Let f_n such that

$$\lim_{n\to\infty} A(f_n) = A^*$$

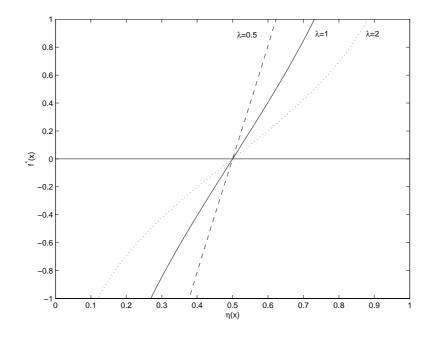

and

$$g_n(x) = \text{sign } f_n(X)$$
.

Then

$$L(g_n) \to L^*$$
 a.s.

Characterization of f_{λ}^*

Proof sketch

Estimation/approximation error decomposition with respect to the cost function ϕ :

$$A(\lambda_n f_n) - A^*$$

$$= \left(A^{\lambda_n} (\widehat{f}_n^{\lambda_n}) - A^{\lambda_n} (\overline{f}_{\lambda_n}) \right) + \left(\inf_{f \in \lambda_n \cdot \mathcal{F}} A(f) - A^* \right)$$

where

$$\overline{f}_{\lambda} = \operatorname*{arg\,min}_{f \in \mathcal{F}} A^{\lambda}(f)$$

Estimation error:

We have

$$A^{\lambda_n}(\widehat{f}_n^{\lambda_n}) - A^{\lambda_n}(\overline{f}_{\lambda_n}) \le 2 \sup_{f \in \mathcal{F}} \left| A^{\lambda}(f) - A_n^{\lambda}(f) \right|$$

$$A^{\lambda_n}(\widehat{f}_n^{\lambda_n}) - A_n^{\lambda_n}(\widehat{f}_n^{\lambda_n})$$

$$A_n^{\lambda_n}(\widehat{f}_n^{\lambda_n}) - A^{\lambda_n}(\overline{f}_{\lambda_n})$$

$$A_n^{\lambda_n}(\widehat{f}_n^{\lambda_n}) - A^{\lambda_n}(\overline{f}_{\lambda_n})$$

$$\le \sup_{f \in \mathcal{F}} \left| A^{\lambda}(f) - A_n^{\lambda}(f) \right|$$

Part I: Denseness

If \mathcal{F} contains the indicators of all subrectangles of \mathbb{R}^d , then

$$\lim_{n \to \infty} \inf_{f \in \lambda \cdot \mathcal{F}} A(f) = A^*$$

where $A^* = \inf A(f)$ over all measurable f.

Part II: Concentration

For any $\delta > 0$, with probability at least $1 - \delta$,

$$\sup_{f \in \mathcal{F}} \left| A^{\lambda}(f) - A_n^{\lambda}(f) \right|$$

$$\leq 4\lambda\phi'(\lambda)\sqrt{\frac{2V\ln(4n+2)}{n}} + \lambda\phi'(\lambda)\sqrt{\frac{\ln(1/\delta)}{2n}}$$
.

(Koltchinskii & Panchenko (2000))

Second result

Strategy based on a penalized criterion is also Bayes-risk consistent.

Formally:

Consider positive $\lambda_k \to +\infty$ and

$$f_n = \underset{k>1}{\operatorname{arg\,min}} \, \tilde{A}_n^{\lambda_k}(\hat{f}_n^{\lambda_k}) ,$$

where

$$\tilde{A}_n^{\lambda_k}(f) = A_n^{\lambda_k}(f) + 5\lambda_k \phi'(\lambda_k) \sqrt{\frac{V \ln n + \ln(nk)}{n}}$$

and

$$\widehat{f}_n^{\lambda_k} = \underset{f \in \mathcal{F}}{\operatorname{arg \, min}} \, A_n^{\lambda_k}(f) \, .$$

Under the denseness assumption, we have

$$\lim_{n \to \infty} L(f_n) = L^* \quad \text{almost surely.}$$

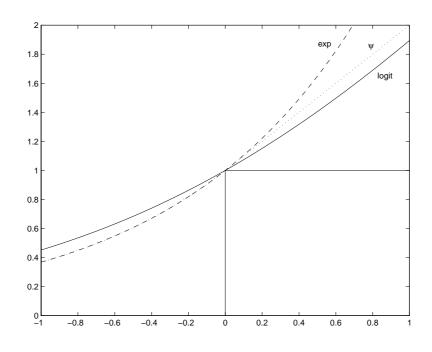

Choices for the cost function

•
$$\phi(x) = \exp(x)$$
,
$$\phi'(\lambda) = \exp(\lambda)$$

• $\phi(x) = \operatorname{logit}(x) := \log_2(1 + \exp(x)),$ $\phi'(\lambda) = \frac{\exp(\lambda)}{1 + \exp(\lambda)}$

•
$$\phi(x) = \psi(x) := \min \{ \exp(x), |x| + 1 \},$$

$$\phi'(\lambda) = 1$$

Simulations

Set-up

- Generate 6-dimensional synthetic data samples of size n = 100, ..., 500 from 'twonorm', 'threenorm', 'ringnorm' generators.
- For each λ , run the boosting algorithm to minimize $A_n^{\lambda}(f)$ over the convex hull of all decision stumps (CPU time from 10 to 50 seconds for 300 iterations).
- Estimate the expected cost $A^{\lambda}(\widehat{f}_n^{\lambda})$ and the generalization error $L(\widehat{f}_n^{\lambda})$ over a test set of size m.

Comments

- influence of the cost function
- comparison of the minimizers
- sensitivity to the level of noise

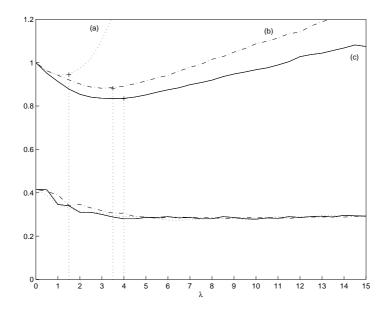

Figure 1: Threenorm. Cost $\phi = \psi$. d = 6. $\eta = 0.1$. n = 100. m = 500. Plot of the cost $A^{\lambda}(\hat{f}_n^{\lambda})$ (upper curves) and test error (lower curves) for various cost functions (a) exp. (b) logit, (c) ψ .

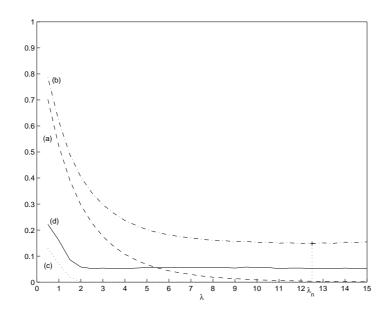

Figure 2: Twonorm. Cost $\phi = \psi$. d = 6. n = 100. m = 500. (a) $A_n^{\lambda}(\hat{f}_n^{\lambda})$. (b) $A^{\lambda}(\hat{f}_n^{\lambda})$. (c) training error. (d) test error.

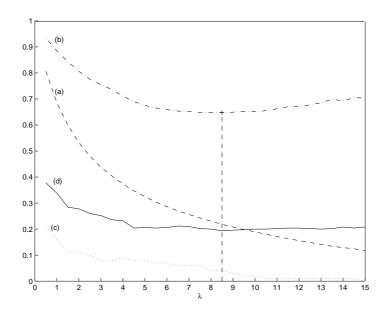

Figure 3: Threenorm. Cost $\phi = \psi$. d = 6. n = 100. m = 500. (a) $A_n^{\lambda}(\hat{f}_n^{\lambda})$. (b) $A^{\lambda}(\hat{f}_n^{\lambda})$. (c) training error. (d) test error.

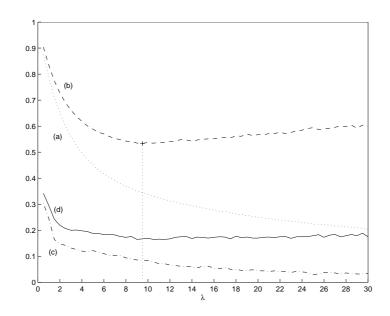

Figure 4: Threenorm. Cost $\phi = \phi$. d = 6. n = 500. m = 1000. (a) $A_n^{\lambda}(\hat{f}_n^{\lambda})$. (b) $A^{\lambda}(\hat{f}_n^{\lambda})$. (c) training error. (d) test error.

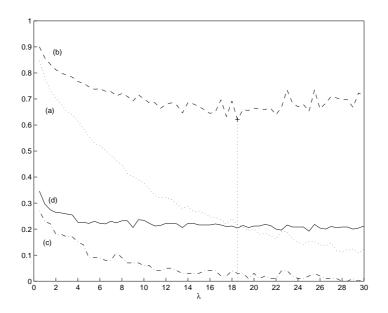

Figure 5: Ringnorm. Cost $\phi = \psi$. d = 6. n = 100. m = 500. (a) $A_n^{\lambda}(\hat{f}_n^{\lambda})$. (b) $A^{\lambda}(\hat{f}_n^{\lambda})$. (c) training error. (d) test error.

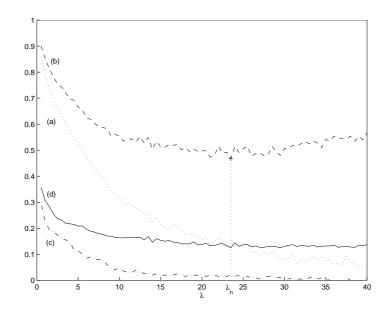

Figure 6: Ringnorm. Cost $\phi = \psi$. d = 6. n = 200. m = 1000. (a) $A_n^{\lambda}(\hat{f}_n^{\lambda})$. (b) $A^{\lambda}(\hat{f}_n^{\lambda})$. (c) training error. (d) test error.

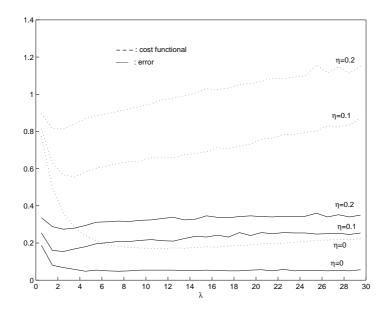

Figure 7: Twonorm. Cost $\phi = \psi$. d = 6. n = 100. m = 500. Plots of $A^{\lambda}(\widehat{f}_n^{\lambda})$ and of the test error for levels of noise $\eta = 0, 0.1, 0.2$.

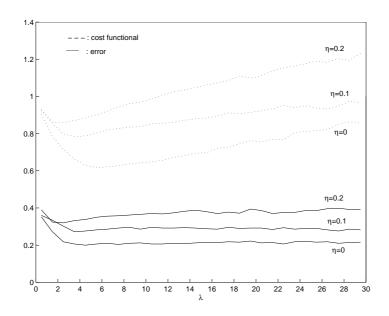

Figure 8: Threenorm. Cost $\phi = \psi$. d = 6. n = 100. m = 500. Plots of $A^{\lambda}(\widehat{f}_{n}^{\lambda})$ and of the test error for levels of noise $\eta = 0, 0.1, 0.2$.

Further work

- Non-asymptotic behavior has to be better understood.
- Rates of convergence for boosting. Use of approximation results.
- Distribution-dependent results.
